AOU Policlinico "G.Martino", Messina

Mario, 4 anni

Esordio di sindrome nefrosica all'età di 3 anni

Sindrome nefrosica cortico-dipendente:
4 recidive in coincidenza della riduzione della terapia steroidea

Terza recidiva a dicembre 2010 complicata da IRA prerenale in concomitanza a gastroenterite

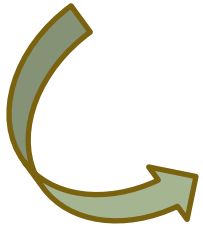
Prednisone 60 mg/mq/die con remissione nelle prime due settimane

Recidiva durante il passaggio del prednisone a gg alterni ad inizio febbraio 2011

Durante l’ultima recidiva (importante ipoalbuminemia con ascite ed edemi periferici) comparsa di dolore inizialmente in sede sacroccigea, successivamente in sede *addominale diffuso, intenso e continuo*

All’E.O. addome uniformemente globoso, notevolmente dolente alla palpazione superficiale e profonda, teso e non trattabile su tutti i quadranti, immobile con respirazione di tipo costale

Evacuazione stimolata (glicerina) nelle 6 ore prima
Da allora alvo chiuso a feci e gas



Quadro di addome acuto

Diagnosi differenziale dell'addome acuto in paziente con recidiva di sindrome nefrosica

- **Trombosi vene renali**
- **Invaginazione intestinale**
- **Peritonite**
- **Colite ischemica**
- **Pneumatosi intestinale**

Procediamo dunque ai vari approfondimenti diagnostici…

Rx addome d'urgenza:

"Si documenta mancata visualizzazione delle anse ileo-coliche, con evidenza di una marcata gastrectasia e di alcune anse digiuno-ileali sede di livelli idroaerei nel contesto"

***Prelievo ematochimico d'urgenza*:**

GB 19.400 mmc, N 87%, L 8%

GR 4.610.000 mmc, Hb 12,9 gr/dl, PLT 555.000 mmc

azotemia 52 mg/dl, creatinina 0,3 mg/dl, proteine totali 3,6 gr/dl

Ca 7,78 mg/dl, Na 132 mmol/l, K 3,6 mmol/l

PCR 1,2 mg/dl (v.n.0,5)

D-dimero 4,34 mg/l (v.n. <0,50)

Nel sospetto di una trombosi della vena renale…

Eco-color-Doppler vasi addominali:
“La vena splenica, la mesenterica superiore ed il tronco portale appaiono pervi. Entrambe le vene renali presentano regolare flussimetria alla valutazione eco color Doppler. Regolare la morfologia dello spettro arterioso dei vasi renali al campionamento delle arterie interlobari”

Ecografia addome:
“Presenza di abbondante versamento ascitico sopra e sottomesocolico. Le anse intestinali, disposte in sede centroaddominale, appaiono alquanto distese da aria. In tali condizioni non è possibile valutare eventuali alterazioni di parete o immagini di invaginazione”

Si tratta di invaginazione intestinale o di colite ischemica?

Consulenza chirurgica:
"In atto addome globoso, dolente alla palpazione profonda, con meteorismo diffuso. Riscontro all'Rx di marcata gastrectasia e all'ecografia di distensione intestinale, motivo per cui si pone sondino NG e si consiglia di non alimentare il bambino. Nuova rivalutazione clinica a breve termine"

Alcune ore dopo l'esordio del dolore addominale…

Comparsa di eritema ombelicale

EPICRISI

- Bambino affetto da SN cortico-dipendente, con due recidive ravvicinate (l'ultima ad alto dosaggio steroideo), importante ipoalbuminemia ed ascite

- Quadro clinico di addome acuto
(resistenza addominale, respirazione superficiale e prevalentemente costale, eritema attorno alla cicatrice ombelicale diffuso poi anche in regione sovrapubica)

-Non febbre

- Eritema cicatrice ombelicale progressivamente diffusosi in regione sovrapubica

Esami di laboratorio
Quadro di SN
Leucocitosi neutrofila
D-dimero
PCR lievemente aumentata

Esclusa la trombosi vascolare,
Poco probabile l'invaginazione intestinale

?

I dubbi

L'eritema ombelicale…
Che significato semeiologico esprime?

Kaohsiung J Med Sci. 2007 Feb;23(2):80-3.

Red umbilicus as a clinical manifestation in a 19-month-old girl with typhoid colonic perforation.

Chang YT, Lin JY.

Division of Pediatric Surgery, Department of Surgery, Kaohsiung Medical University Hospital, and Department of Surgery, Faculty of Medicine, College of Medicine, Kaohsiung Medical University, Kaohsiung, Taiwan.

Abstract

Redness of the umbilicus is usually considered to be a reliable sign of underlying gangrenous bowel or peritonitis in tiny infants but seldom among non-neonatal patients. We report a 19-month-old girl with final diagnosis of typhoid colonic perforation who initially presented with abdominal distention and umbilical erythema on arrival at our emergency department. The redness of umbilicus diminished gradually after laparotomy. Thin abdominal wall, severe intra-abdominal soiling, and polymicrobial infection accounted for the inflammatory process spreading to the skin of the umbilicus. Because of its rarity beyond the neonatal period, prompt diagnosis depends on maintaining a high index of suspicion when the abdomen is distended and suddenly tender to palpation.

Ipotesi:... PERITONITE PRIMITIVA SPONTANEA

Terapia antibiotica ev con:
- Metronidazolo (7,5 mg/kg/dose x 3 vv/die)
- Ceftazidime (100 mg/kg/die)

Terapia d'attacco della SN:
- Albumina
- Plasma
- Furosemide
-Calcio gluconato
- *Sospesi momentaneamente i boli di cortisone*

Andamento della PCR
0,10 mg/dl (all'esordio della recidiva di SN)
1,20 mg/dl (all'esordio dei sintomi addominali)
12,9 mg/dl (12 h ore dopo)

Teicoplanina: dose carico 10 mg/kg/ogni 12 ore per le prime 3 somministrazioni, poi 10 mg/kg/die

24 ore dopo: **PCR 21,10** mg/dl

Risoluzione del quadro clinico addominale dopo 48 h dalla comparsa della sintomatologia algica con progressivo miglioramento delle condizioni cliniche generali

Graduale riduzione degli indici di flogosi e della leucocitosi neutrofila:

	06/02	***07/02***	***11/02***	***12/02***
GB (mmc)	23.000	12.200	9.000	7.000
N%	82	78	60	56
L%	12	16	33	25
PCR (mg/dl)	21,1	15,3	0,20	0,10

Canalizzazione intestinale spontanea normalizzatasi solo dopo una settimana

Complicanze nella fase d’esordio o recidiva della sindrome nefrosica

INFEZIONI

TROMBOSI

LE COMPLICANZE INFETTIVE NELLA SN

I soggetti affetti da SN sono più ***suscettibili*** alle infezioni a causa di numerosi meccanismi patogenetici legati alla loro malattia di base:

- riduzione di Ig
- disfunzione di fattori implicati nell'attivazione del complemento (perdita dei fattori B e D del complemento) e della fagocitosi
- alterata funzione di cellule T ed in particolar modo dell'immunità cellulo-mediata
- trattamento immunosoppressivo prolungato

GERMI MAGGIORMENTE RESPONSABILI

- bambini: pneumococco
- adulti: gram negativi

VARIE LOCALIZZAZIONI

- Polmonite
- Osteomielite
- Peritonite
- Cellulite

REV. HOSP. CLÍN. FAC. MED. S. PAULO 59(5):273-278, 2004

Predictors of peritonitis in children with nephrotic syndrome

Caratteristiche della peritonite nella SN in letteratura

- Spesso la peritonite primitiva avviene nei primi 2 anni della SN
- Sempre in fase di esordio o recidiva
- Più severa è l'ipoalbuminemia e maggiore è il rischio
- Spesso la paracentesi non viene effettuata per la gravità delle condizioni cliniche del bambino, ma anche per un rapporto benefici/rischi sfavorevole (mancata identificazione di germe, sovrainfezioni fungine…)
- Il germe più frequentemente responsabile è lo Streptococco pneumoniae ma sono descritti anche germi gram-negativi

Pediatr Nephrol. 1995 Aug;9(4):411.

How would you treat a 4-year-old boy with nephrotic syndrome in relapse with ascites developed peritonitis and abdominal pain?

Potter DE.

University of California, San Francisco School of Medicine, Department of Pediatrics 94143-0748, USA.

Ask the expert*

A 4-year-old boy with nephrotic syndrome in relapse with ascites developed peritonitis and abdominal pain. Paracentesis of the abdomen revealed turbid fluid with a large number of white cells, but no growth on culture in spite of there being no previous history of administration of antibiotics. What treatment would you advise?

Key words: Nephrotic syndrome – Ascites – Peritonitis – Treatment

A third-generation cephalosporin for 10–14 days. In two large series of children with nephrotic syndrome and documented peritonitis, only 43% [1] and 54% [2] had positive peritoneal fluid cultures, although an additional 18% and 29%, respectively, had positive blood cultures. Of the bacteria cultured, the pneumococcus predominated, 77% and 60% respectively, whereas other streptococcal species accounted for 13% and 5%, respectively, and Gram-negative rods, mostly *Escherichia coli*, accounted for 9% and 35%, respectively. *Haemophilus influenza* has been an uncommon pathogen.

The combination of penicillin and an aminoglycoside has been the recommended therapy for children with nephrotic syndrome and culture-negative peritonitis. A third-generation cephalosporin is effective against virtually all of the organisms implicated in nephrotic syndrome-associated peritonitis, however, and has the advantage of monotherapy. The emergence of penicillin-resistant strains of pneumococci also makes a third-generation cephalosporin an attractive choice, although pneumococcal resistance to cephalosporins as well as penicillin has recently been reported [3].

Although chemoprophylaxis with penicillin is shown to reduce the incidence of pneumococcal infections in children with sickle cell disease, there are no controlled trials on the use of penicillin prophylaxis in children with NS [15]. Penicillin prophylaxis has been used sporadically in nephrotic children, and peritonitis was reported in children both with and without penicillin prophylaxis. In our series, none of the peritonitis cases received penicillin prophylaxis.

dependent, steroid-resistant, or frequent relapsers. We suggest that it makes possible sense to administer a polyvalent vaccine to children switching to either steroid-dependent, steroid-resistant, or frequently relapsing forms of NS within 2 years after the beginning of the disease.

Prevention of Pneumococcal Disease Among Infants and Children — Use of 13-Valent Pneumococcal Conjugate Vaccine and 23-Valent Pneumococcal Polysaccharide Vaccine

Abdominal complications in black and Indian children with nephrotic syndrome.

Adhikari M, Coovadia HM.

Department of Paediatrics and Child Health, University of Natal, Durban.

Abstract

Abdominal complications were detected and investigated in 19 (10%) of 191 children with nephrotic syndrome who experienced 35 episodes of these complications. Fourteen children were Indian with steroid-responsive nephrotic syndrome, and 5 were black, of whom 4 had membranous nephropathy and 1 focal proliferative nephritis. All had clinical features of peritonitis and hypovolaemia was frequently present. Eleven of the 35 episodes were culture-proven peritonitis (5 due to Pneumococcus, 6 due to Gram-negative bacteria) and in 24 the cultures were negative. Hypovolaemia occurred in 6 of the former group and 5 of the latter. The occurrence of these episodes bore no temporal relationship to steroid and cyclophosphamide treatment. Sixty-nine per cent of the complications appeared within the first 3 years of onset of the nephrotic syndrome and 8 of 19 patients experienced multiple episodes. In this study, hypovolaemia always occurred in the context of clinically detected peritonitis and not as a separate complication, suggesting infection together with fluid and protein losses as likely pathogenetic mechanisms.

3 pazienti sviluppavano peritonite dopo vaccinazione anti-pneumococcica

Relationship between proteinuria and venous thromboembolism.

Kato S, Chernyavsky S, Tokita JE, Shimada YJ, Homel P, Rosen H, Winchester JF.

Department of Medicine, Beth Israel Medical Center, University Hospital and Manhattan Campus for the Albert Einstein College of Medicine, First Avenue at 16th Street, New York, NY 10003, USA. shkato@chpnet.org

Abstract

Nephrotic syndrome is known to cause venous thromboembolism (VTE) due to urine loss of antithrombin III and activation of the coagulation system. We hypothesized that the degree of proteinuria may predict the development of VTE. This was a retrospective case-controlled study of in-patients urban academic teaching hospital from April, 2007 to March, 2009 and who had undergone an imaging study for VTE. All radiology reports (N = 1,647) for CT angiography of chest and Doppler sonogram of extremities were reviewed. The following data were collected: race/ethnicity, degree of proteinuria on urinalysis, serum protein and albumin levels, risk factors for VTE and renal function. The study population consisted of 284 patients with VTE and 280 age/sex matched controls. Relative to those who did not have proteinuria, patients who tested positive for protein had a 3.4-fold increased risk of VTE (odds ratio (OR) 3.4, 95% confidence interval [2.4, 5.0]). The association was unchanged when adjusted for other risk factors. Patients with proteinuria may have an increased risk of venous thromboembolism.

CONCLUSIONI:

- I livelli di proteinuria rappresentano il parametro maggiormente correlato al rischio di trombosi
- La terapia si basa sull'uso di alte dosi di eparina da mettere in relazione ai bassi livelli di ATII
- La profilassi con anticoagulanti orali è efficace nella prevenzione di recidive della trombosi

PREVENZIONE DELLA TROMBOSI IN CORSO DI SINDROME NEFROSICA

Ischemic colitis as a complication in a patient with steroid-dependent nephrotic syndrome.

Yanagisawa A, Namai Y, Sekine T, Igarashi T.

Department of Pediatrics, Ohta Nishinouchi Hospital, Fukushima, Japan.

Abstract

We report the case of a 16-year-old male patient with steroid-dependent nephrotic syndrome who developed ischemic colitis. He was diagnosed as having nephrotic syndrome at 10 years of age and had been administered steroid, cyclosporine A, and mizoribine for 7 years. He presented with severe abdominal pain 5 days after intravenous methylprednisolone pulse therapy; thereafter, massive bloody diarrhea developed. Abdominal ultrasonography and computed tomography revealed a marked thickening of the wall of the transverse colon. Colonoscopy confirmed the diagnosis of ischemic colitis. This is the first report of the development of ischemic colitis in a pediatric patient with nephrotic syndrome.

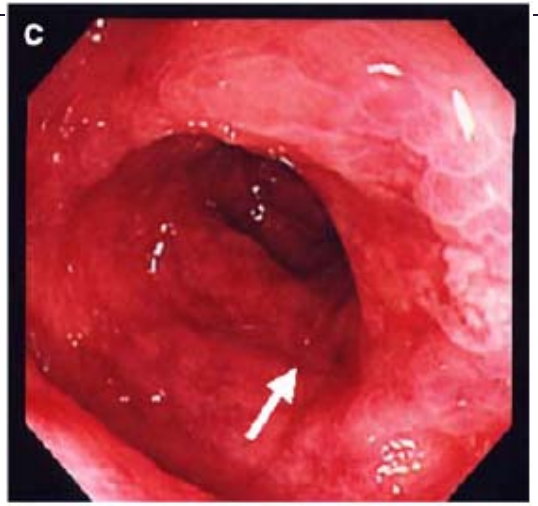

Figure 2. **Transverse section of abdominal CT.**
Massive air in the intestinal wall caused narrowing of the lumen.

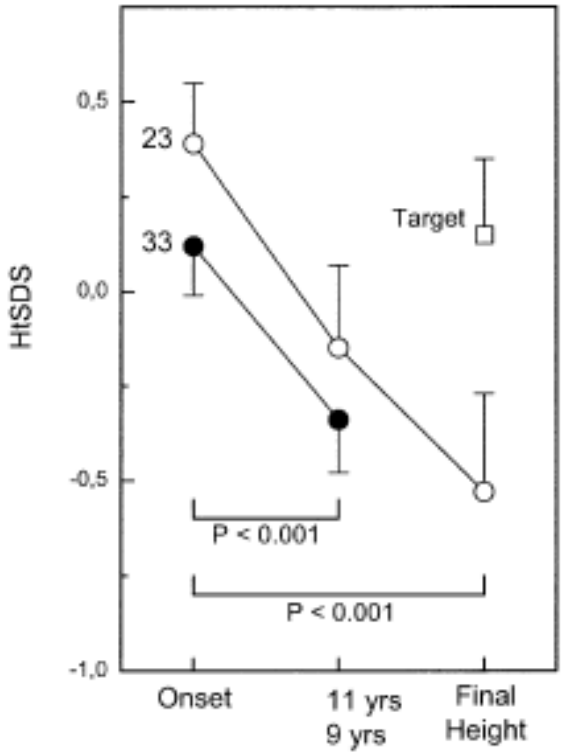
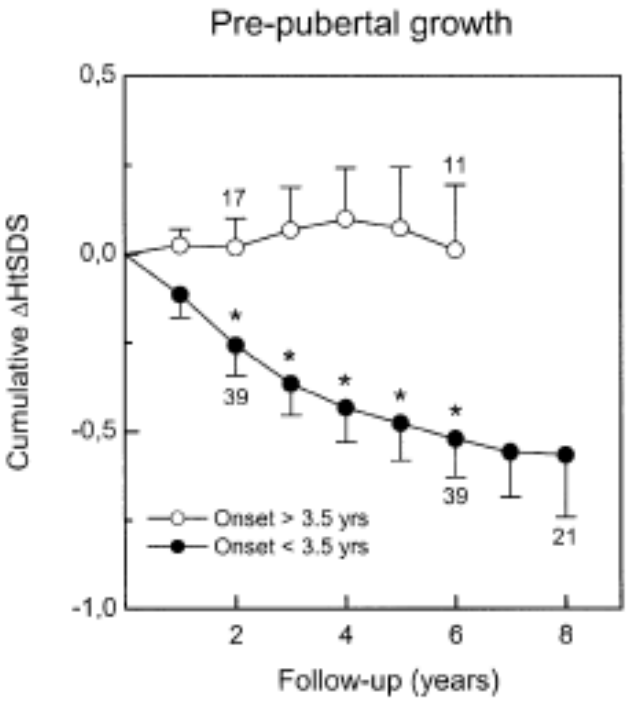
Long-term linear growth of children with severe steroid-responsive nephrotic syndrome

42 SN steroido-dipendente

14 SN frequenti recidive





Long-Term, High-Dose Glucocorticoids and Bone Mineral Content in Childhood Glucocorticoid-Sensitive Nephrotic Syndrome

Mary B. Leonard, M.D., M.S.C.E., Harold I. Feldman, M.D., M.S.C.E., Justine Shults, Ph.D., Babette S. Zemel, Ph.D., Bethany J. Foster, M.D., M.S.C.E., and Virginia A. Stallings, M.D.

N Engl J Med 2004;351:868-75.

Il trattamento con cortisone ad alti dosaggi, ma a giorni alterni, durante il periodo di crescita, non sembra determinare deficit significativi nel contenuto minerale osseo valutato con densitometria della colonna verticale

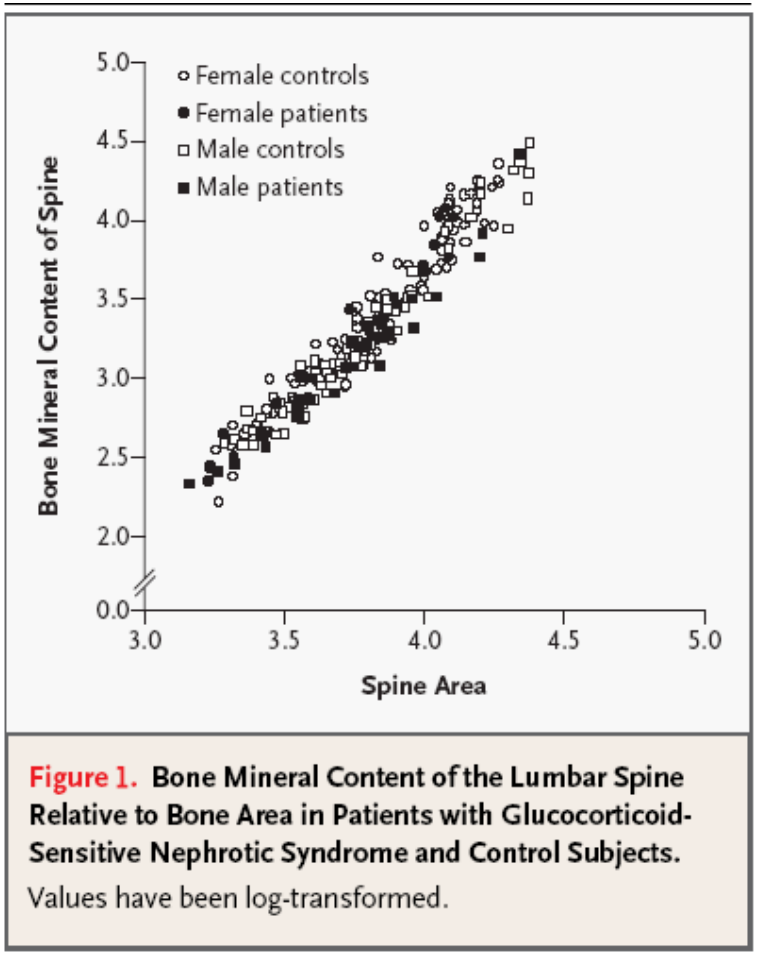


Figure 1. Bone Mineral Content of the Lumbar Spine Relative to Bone Area in Patients with Glucocorticoid-Sensitive Nephrotic Syndrome and Control Subjects.
Values have been log-transformed.

Casistica studiata

- **26 bambini con SN corticosensibile (ISKDC)**
- **età media: 6.9 ± 2.5 anni**
- **sesso: 19M/7F**
- **follow-up: 38.5 ± 8 mesi**

Trattamento

Prednisone 60 mg/mq/die per 4 settimane progressivamente ridotto per una durata complessiva all'esordio di 4 mesi e mezzo

26 bambini con SN corticosensibile

16 con SN infrequenti recidive (SNIR)

10 con SN frequenti recidive (SNFR) o corticodipendente (SNCD)

Materiali e Metodi

Ogni 3 mesi:

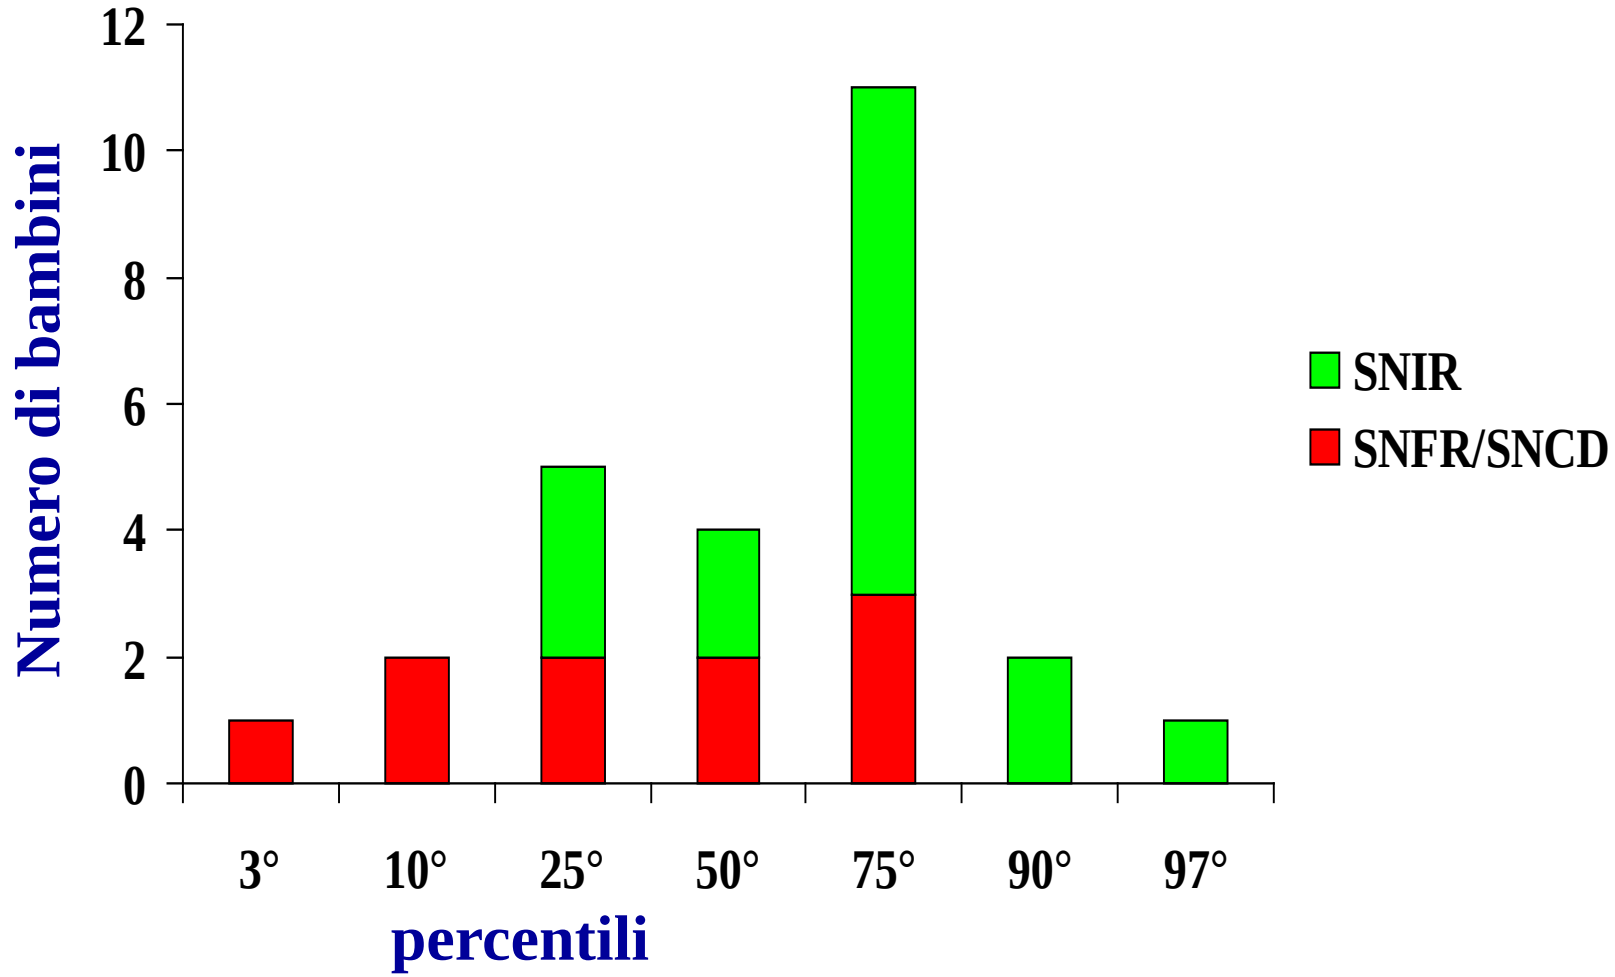
- **statura**
- **velocità di crescita staturale**

Ogni 6 mesi:

- **parametri ematochimici (Ca, P, ALP, PTH)**
- **Calciuria/Creatininuria**
- **densitometria ossea a livello del calcagno, con apparecchio ad ultrasuoni (Osteospace – Medi Link)**

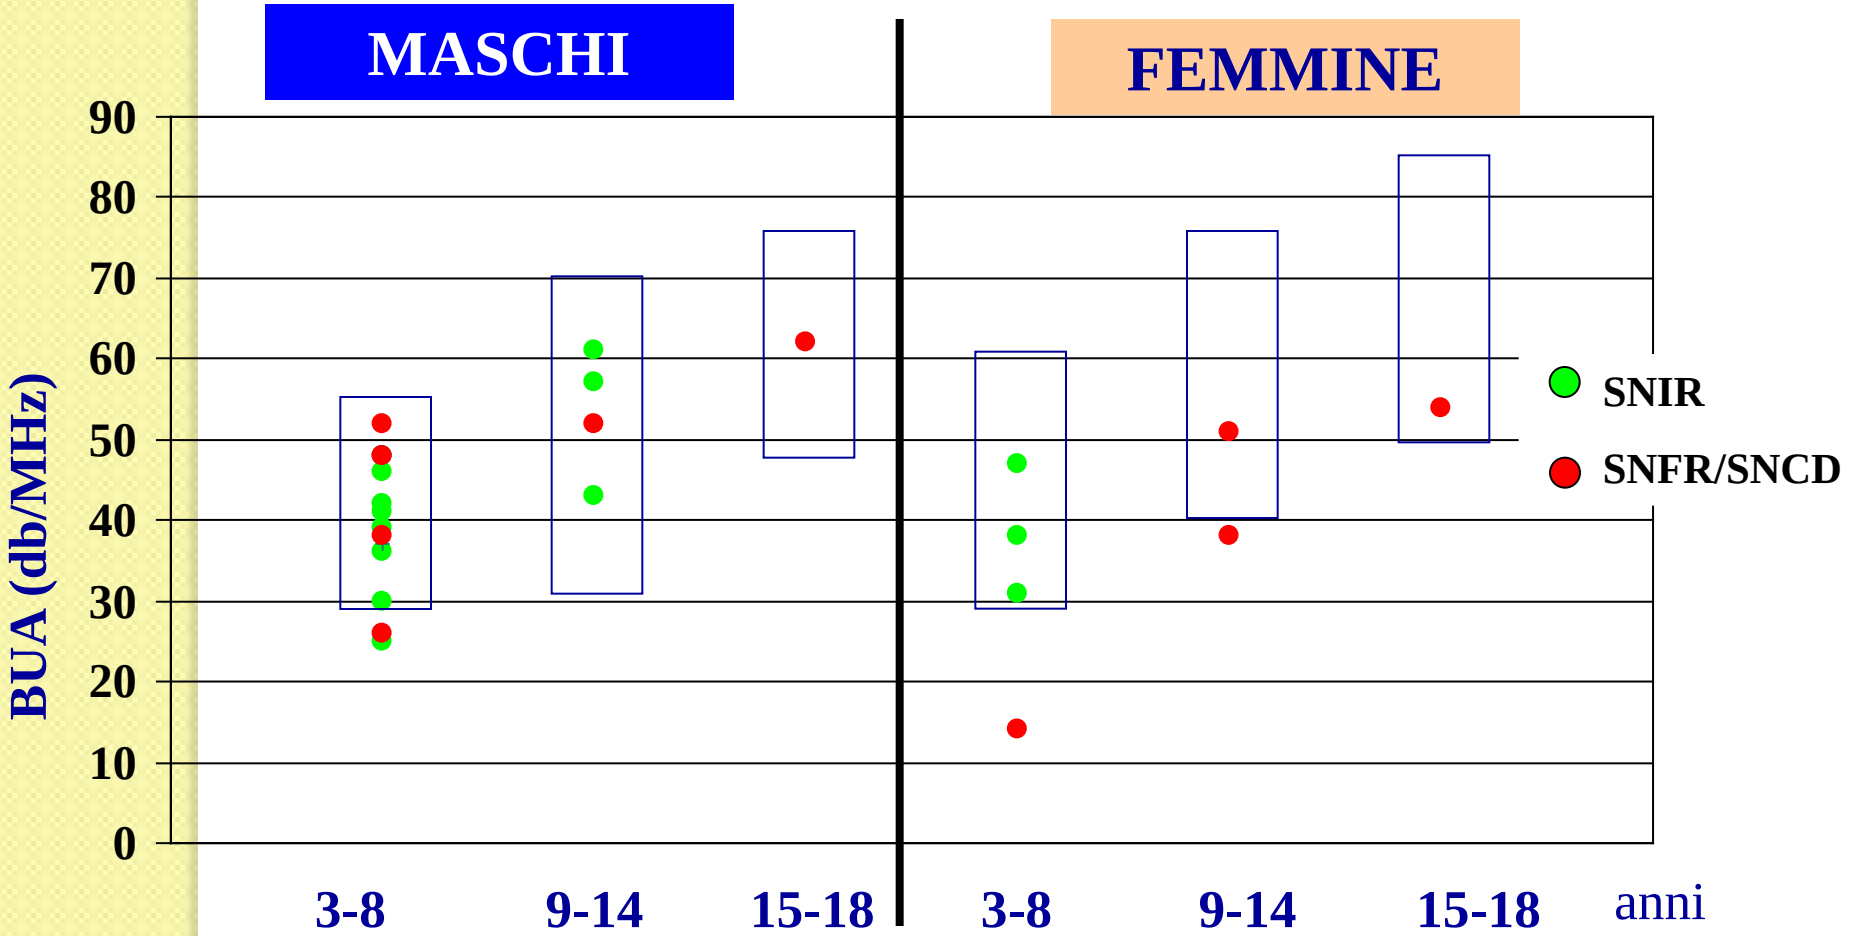
(Calcif Tissue Int. 2000; 67:19-23) (Eur J Pediatr. 2003; 162: 776-780)

Valutazione della statura in percentili in bambini affetti da sindrome nefrosica ad infrequenti recidive (SNIR) e a frequenti recidive (SNFR) o cortico-dipendenti (SNCD)



UO Nefrologia e Reumatologia Pediatrica con Dialisi- Messina

Valutazione della densità ossea in densitometria eseguita a livello del calcagno in bambini affetti da sindrome nefrosica ad infrequenti recidive (SNIR) e a frequenti recidive (SNFR) o cortico-dipendenti (SNCD).



Non abbiamo trovato correlazioni significative tra i parametri valutati ed il dosaggio steroideo complessivo o il numero di recidive

	SNIR	SNFR/SNCD
Statura <25°perc	0/16	3/10
Densità ossea -2DS	1/16	3/10
Velocità di crescita -2DS	0/16	1/10

EDITORIAL COMMENTARY

Rituximab: is replacement of cyclophosphamide and calcineurin inhibitors in steroid-dependent nephrotic syndrome possible?

Jörg Dötsch · Dirk. E. Müller-Wiefel · Markus J. Kemper

Rituximab utilizzato in > 500.000 soggetti

Tossicità, effetti colaterali:

- **2 casi di leucoenecefalite in LES trattati con multiterapia , incluso Rituximab**
- **Reazioni allergiche,**
